Attributes

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
        self.name = f"{first} {last}"
```

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
        self.name = f"{first} {last}"
```

Attribute name
depends on other
attributes.

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
        self.name = f"{first} {last}"
```

```
john = Person("John", "Doe")  
print(john.name) # John Doe
```

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
        self.name = f"{first} {last}"
```

```
john = Person("John", "Doe")  
print(john.name) # John Doe  
john.last = "Smith"  
print(john.name) # ???
```

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
        self.name = f"{first} {last}"
```

```
john = Person("John", "Doe")  
print(john.name) # John Doe  
john.last = "Smith"  
print(john.name) # John Doe
```

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
        self.name = f"{first} {last}"
```

```
john = Person("John", "Doe")  
print(john.name) # John Doe  
john.last = "Smith"  
print(john.name) # John Doe
```

Person.name:

- has dependencies; but
- only computed once.

Dynamic attribute computation

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
        self.name = f"{self.first} {self.last}"
```

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
  
    def name(self):  
        return f"{self.first} {self.last}"
```

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
  
    @property  
    def name(self):  
        return f"{self.first} {self.last}"
```

```
class Person:                                john = Person("John", "Doe")
    def __init__(self, first, last):
        self.first = first
        self.last = last

    @property
    def name(self):
        return f"{self.first} {self.last}"
```

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last
```

@property

```
def name(self):  
    return f"{self.first} {self.last}"
```

```
john = Person("John", "Doe")  
print(john.name)
```

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
  
    @property  
    def name(self):  
        return f"{self.first} {self.last}"
```

```
john = Person("John", "Doe")  
print(john.name)
```

Accessing the
attribute calls
the method.

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last
```

@property

```
def name(self): ←  
    return f"{self.first} {self.last}"
```

```
john = Person("John", "Doe")  
print(john.name) # John Doe
```

Accessing the
attribute calls
the method.

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last
```

@property
def name(self):
 return f"{self.first} {self.last}"

```
john = Person("John", "Doe")  
print(john.name) # John Doe  
john.last = "Smith"  
print(john.name) # ???
```

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
  
    @property  
    def name(self): ←  
        return f"{self.first} {self.last}"
```

```
john = Person("John", "Doe")  
print(john.name) # John Doe  
john.last = "Smith"  
print(john.name) # John Smith
```

Because we call the method, the value is recomputed.

`@property` “turns methods into attributes.”

Your first
descriptor

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
  
    @property  
    def name(self):  
        return f"{self.first} {self.last}"
```

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last
```

@property
def name(self):
 return f"{self.first} {self.last}"

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last
```

```
class NameDescriptor:
```

...

We create a class for the descriptor.

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
  
    @property  
    def name(self):  
        return f"{self.first} {self.last}"
```

```
class Person:  
    name = NameDescriptor()  
  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
  
class NameDescriptor:  
    ...
```

We assign the descriptor to
the class attribute name.

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
  
    @property  
    def name(self):  
        return f"{self.first} {self.last}"
```

```
class Person:  
    name = NameDescriptor()  
  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
  
class NameDescriptor:  
    def __get__(self, person, cls):  
        ...
```

The dunder method `__get__` is called
when we try to “get” the attribute...

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
  
    @property  
    def name(self):  
        return f"{self.first} {self.last}"
```

```
class Person:  
    name = NameDescriptor()  
  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
  
class NameDescriptor:  
    def __get__(self, person, cls):  
        return f"{person.first} {person.last}"
```

... so it must return the computed value.

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
  
    @property  
    def name(self):  
        return f'{self.first} {self.last}'
```

get in action

```
class Person:  
    name = NameDescriptor()  
  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
  
class NameDescriptor:  
    def __get__(self, person, cls):  
        return f'{person.first} {person.last}'
```

... so it must return the computed value.

```
class Person:  
    name = NameDescriptor()  
  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
  
class NameDescriptor:  
    def __get__(self, person, cls):  
        print("Inside __get__") ←  
        return f"{person.first} {person.last}"
```

Added a helper print.

```
class Person:                                     >>> john = Person("John", "Doe")
    name = NameDescriptor()

    def __init__(self, first, last):
        self.first = first
        self.last = last

class NameDescriptor:
    def __get__(self, person, cls):
        print("Inside __get__")
        return f"{person.first} {person.last}"
```

```
class Person:  
    name = NameDescriptor() ←  
  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
  
class NameDescriptor:  
    def __get__(self, person, cls):  
        print("Inside __get__")  
        return f"{person.first} {person.last}"  
  
    >>> john = Person("John", "Doe")  
    >>> john.name
```

```
class Person:  
    name = NameDescriptor() ←  
  
def __init__(self, first, last):  
    self.first = first  
    self.last = last  
  
class NameDescriptor:  
    def __get__(self, person, cls):  
        print("Inside __get__")  
        return f"{person.first} {person.last}"  
  
>>> john = Person("John", "Doe")  
>>> john.name
```

```
class Person:  
    name = NameDescriptor()  
  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
  
class NameDescriptor:  
    def __get__(self, person, cls):  
        print("Inside __get__")  
        return f"{person.first} {person.last}"  
  
>>> john = Person("John", "Doe")  
>>> john.name  
Inside __get__  
'John Doe'
```

```
class Person:  
    name = NameDescriptor()  
  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
  
  
class NameDescriptor:  
    def __get__(self, person, cls):  
        print("Inside __get__")  
        return f"{person.first} {person.last}"
```

```
>>> john = Person("John", "Doe")  
>>> john.name  
Inside __get__  
'John Doe'  
>>> john.last = "Smith"
```

```
class Person:  
    name = NameDescriptor()  
  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
  
class NameDescriptor:  
    def __get__(self, person, cls):  
        print("Inside __get__")  
        return f"{person.first} {person.last}"
```

```
>>> john = Person("John", "Doe")  
>>> john.name  
Inside __get__  
'John Doe'  
>>> john.last = "Smith"  
>>> john.name  
Inside __get__  
'John Smith'
```

The descriptor's `__get__` runs
when we access the attribute.

A more general
descriptor

```
>>> red = Colour("#ff0000")
```

```
>>> red = Colour("#ff0000")
>>> red.r
255
```

```
>>> red = Colour("#ff0000")
>>> red.r
255
>>> red.g, red.b
(0, 0)
```

```
class Colour:  
    def __init__(self, hex_repr):  
        self.hex = hex_repr  
  
>>> red = Colour("#ff0000")  
>>> red.r  
255  
>>> red.g, red.b  
(0, 0)
```

```
class Colour:  
    def __init__(self, hex_repr):  
        self.hex = hex_repr  
  
    @property  
    def r(self):  
        return int(self.hex[1:3], 16)  
  
>>> red = Colour("#ff0000")  
>>> red.r  
255  
>>> red.g, red.b  
(0, 0)
```

```
class Colour:  
    def __init__(self, hex_repr):  
        self.hex = hex_repr  
  
    @property  
    def r(self):  
        return int(self.hex[1:3], 16)  
  
    @property  
    def g(self):  
        return int(self.hex[3:5], 16)  
  
>>> red = Colour("#ff0000")  
>>> red.r  
255  
>>> red.g, red.b  
(0, 0)
```

```
class Colour:  
    def __init__(self, hex_repr):  
        self.hex = hex_repr  
  
    @property  
    def r(self):  
        return int(self.hex[1:3], 16)  
  
    @property  
    def g(self):  
        return int(self.hex[3:5], 16)  
  
    @property  
    def b(self):  
        return int(self.hex[5:7], 16)  
  
>>> red = Colour("#ff0000")  
>>> red.r  
255  
>>> red.g, red.b  
(0, 0)
```

The properties only
differ in the slice.

```
class Colour:  
    def __init__(self, hex_repr):  
        self.hex = hex_repr  
  
    @property  
    def r(self):  
        return int(self.hex[1:3], 16)  
  
    @property  
    def g(self):  
        return int(self.hex[3:5], 16)  
  
    @property  
    def b(self):  
        return int(self.hex[5:7], 16)
```

The properties only differ in the slice.

We can replace them with a single descriptor.

```
class Colour:  
    def __init__(self, hex_repr):  
        self.hex = hex_repr  
  
    @property  
    def r(self):  
        return int(self.hex[1:3], 16)  
  
    @property  
    def g(self):  
        return int(self.hex[3:5], 16)  
  
    @property  
    def b(self):  
        return int(self.hex[5:7], 16)
```

```
class Colour:  
    r = # ...  
    g = # ...  
    b = # ...  
  
    def __init__(self, hex_repr):  
        self.hex = hex_repr
```

Class attributes that
will be assigned the
descriptor.

```
class Colour:  
    def __init__(self, hex_repr):  
        self.hex = hex_repr  
  
    @property  
    def r(self):  
        return int(self.hex[1:3], 16)  
  
    @property  
    def g(self):  
        return int(self.hex[3:5], 16)  
  
    @property  
    def b(self):  
        return int(self.hex[5:7], 16)
```

```
class Colour:  
    r = RGBComponent(...)  
    g = RGBComponent(...)  
    b = RGBComponent(...)  
  
def __init__(self, hex_repr):  
    self.hex = hex_repr
```

```
class Colour:  
    def __init__(self, hex_repr):  
        self.hex = hex_repr  
  
    @property  
    def r(self):  
        return int(self.hex[1:3], 16)  
  
    @property  
    def g(self):  
        return int(self.hex[3:5], 16)  
  
    @property  
    def b(self):  
        return int(self.hex[5:7], 16)
```

A class for the
descriptor.

```
class Colour:  
    r = RGBComponent(...)  
    g = RGBComponent(...)  
    b = RGBComponent(...)  
  
def __init__(self, hex_repr):  
    self.hex = hex_repr
```

```
class RGBComponent:  
    def __init__(self, start, end):  
        self.start = start  
        self.end = end
```

We specify the component
via the `__init__`.

```
class Colour:  
    def __init__(self, hex_repr):  
        self.hex = hex_repr  
  
    @property  
    def r(self):  
        return int(self.hex[1:3], 16)  
  
    @property  
    def g(self):  
        return int(self.hex[3:5], 16)  
  
    @property  
    def b(self):  
        return int(self.hex[5:7], 16)
```

```
class Colour:  
    r = RGBComponent(1, 3)  
    g = RGBComponent(...)  
    b = RGBComponent(...)  
  
def __init__(self, hex_repr):  
    self.hex = hex_repr
```

```
class RGBComponent:  
    def __init__(self, start, end):  
        self.start = start  
        self.end = end
```

We specify the component
via the `__init__`.

```
class Colour:  
    def __init__(self, hex_repr):  
        self.hex = hex_repr  
  
    @property  
    def r(self):  
        return int(self.hex[1:3], 16)  
  
    @property  
    def g(self):  
        return int(self.hex[3:5], 16)  
  
    @property  
    def b(self):  
        return int(self.hex[5:7], 16)
```

```
class Colour:  
    r = RGBComponent(1, 3)  
    g = RGBComponent(3, 5)  
    b = RGBComponent(5, 7)  
  
def __init__(self, hex_repr):  
    self.hex = hex_repr
```

```
class RGBComponent:  
    def __init__(self, start, end):  
        self.start = start  
        self.end = end
```

We specify the component
via the `__init__`.

```
class Colour:  
    def __init__(self, hex_repr):  
        self.hex = hex_repr  
  
    @property  
    def r(self):  
        return int(self.hex[1:3], 16)  
  
    @property  
    def g(self):  
        return int(self.hex[3:5], 16)  
  
    @property  
    def b(self):  
        return int(self.hex[5:7], 16)
```

```
class RGBComponent:  
    def __init__(self, start, end):  
        self.start = start  
        self.end = end
```

```
class RGBComponent:  
    def __init__(self, start, end):  
        self.start = start  
        self.end = end  
  
    def __get__(self, colour, cls):  
        return int(  
            colour.hex[self.start:self.end],  
            16,  
        )
```

__get__ replaces the three properties.

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last
```

Dynamic attribute assignment

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
  
    @property  
    def name(self):  
        return f"{self.first} {self.last}"
```

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
  
    @property  
    def name(self):  
        return f"{self.first} {self.last}"  
  
    @name.setter  
    def name(self, new_name):  
        self.first, self.last = new_name.split()
```

Properties can be used
to set attributes, too.

Added a helper print.

```
class Person:  
    def __init__(self, first, last):  
        self.first = first  
        self.last = last  
  
    @property  
    def name(self):  
        return f"{self.first} {self.last}"  
  
    @name.setter  
    def name(self, new_name):  
        → print("Setting the name!")  
        self.first, self.last = new_name.split()
```

```
>>> john = Person("John", "Doe")
```

```
class Person:
    def __init__(self, first, last):
        self.first = first
        self.last = last

    @property
    def name(self):
        return f"{self.first} {self.last}"

    @name.setter
    def name(self, new_name):
        print("Setting the name!")
        self.first, self.last = new_name.split()
```

```
>>> john = Person("John", "Doe")
>>> john.name = "Charles Smith"
Setting the name!
```

```
class Person:
    def __init__(self, first, last):
        self.first = first
        self.last = last

    @property
    def name(self):
        return f"{self.first} {self.last}"

    @name.setter
    def name(self, new_name):
        print("Setting the name!")
        self.first, self.last = new_name.split()
```

```
>>> john = Person("John", "Doe")
>>> john.name = "Charles Smith"
Setting the name!
>>> john.first
'Charles'
>>> john.last
'Smith'
```

```
class Person:
    def __init__(self, first, last):
        self.first = first
        self.last = last

    @property
    def name(self):
        return f"{self.first} {self.last}"

    @name.setter
    def name(self, new_name):
        print("Setting the name!")
        self.first, self.last = new_name.split()
```

```
class Person:  
    ...  
  
    @name.setter  
    def name(self, new_name):  
        self.first, self.last = \  
            new_name.split()
```

Dynamic attribute assignment

```
class Person:  
    @name.setter  
    def name(self, new_name):  
        self._name = new_name.split()
```

Dynamic attribute

```
class Person:  
    ...  
  
    def name(self, new_name):  
        self.first, self.last = \  
            new_name.split()  
  
    @property  
    def name(self):  
        return f'{self.last}, {self.first}'
```

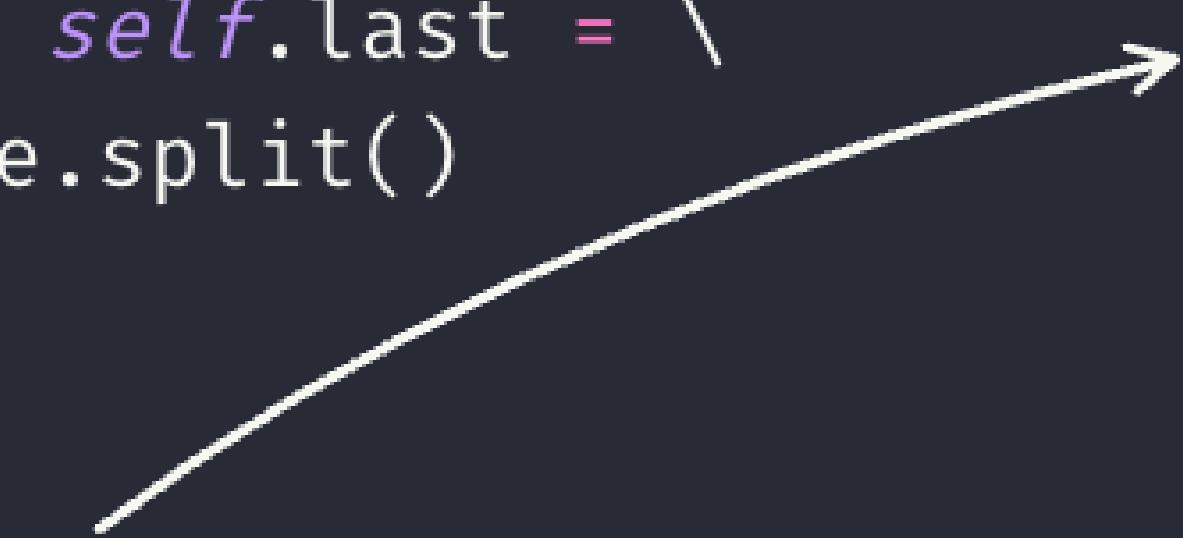

assignment with descriptors

```
class Person:  
    ...  
  
    @name.setter  
    def name(self, new_name):  
        self.first, self.last = \  
            new_name.split()
```

```
class Person:  
    name = NameDescriptor()  
    ...  
  
class Person:  
    ...  
  
    @name.setter  
    def name(self, new_name):  
        self.first, self.last = \  
            new_name.split()
```

```
class NameDescriptor:  
    ...
```

```
class Person:  
    name = NameDescriptor()  
    ...  
  
class Person:  
    ...  
  
    @name.setter  
    def name(self, new_name):  
        self.first, self.last = \  
            new_name.split()  
  
class NameDescriptor:  
    ...  
  
    def __set__(self, person, new_name):  
        ...
```

__set__ is responsible for setting attributes.

```
class Person:  
    name = NameDescriptor()  
    ...  
  
class Person:  
    ...  
  
    @name.setter  
    def name(self, new_name):  
        self.first, self.last = \  
            new_name.split()  
  
class NameDescriptor:  
    ...  
  
    def __set__(self, person, new_name):  
        person.first, person.last = \  
            new_name.split()
```

It mirrors the setter method.

```
class Person:  
    name = NameDescriptor()  
  
...  
  
class NameDescriptor:  
    ...  
  
    def __set__(self, person, new_name):  
        print("Inside __set__")  
        person.first, person.last = \  
            new_name.split()
```

__set__ in action

```
class Person:  
    name = NameDescriptor()  
    ...  
  
class NameDescriptor:  
    ...  
  
    def __set__(self, person, new_name):  
        print("Inside __set__")  
        person.first, person.last = \  
            new_name.split()
```

```
class Person:                                     >>> john = Person("John", "Doe")
    name = NameDescriptor()
    ...
    ...
class NameDescriptor:
    ...
def __set__(self, person, new_name):
    print("Inside __set__")
    person.first, person.last = \
        new_name.split()
```

```
class Person:  
    name = NameDescriptor()  
    ...
```

```
class NameDescriptor:  
    ...
```

```
def __set__(self, person, new_name):  
    print("Inside __set__")  
    person.first, person.last = \  
        new_name.split()
```

```
>>> john = Person("John", "Doe")  
>>> john.name = "Charles Smith"
```

```
class Person:  
    name = NameDescriptor()  
    ...
```

```
class NameDescriptor:  
    ...
```

```
def __set__(self, person, new_name):  
    print("Inside __set__")  
    person.first, person.last = \  
        new_name.split()
```

```
>>> john = Person("John", "Doe")  
>>> john.name = "Charles Smith"  
Inside __set__
```

Assignment triggered
the dunder method
set.

```
class Person:  
    name = NameDescriptor()  
...  
  
class NameDescriptor:  
...  
  
def __set__(self, person, new_name):  
    print("Inside __set__")  
    person.first, person.last = \  
        new_name.split()
```

```
>>> john = Person("John", "Doe")  
>>> john.name = "Charles Smith"  
Inside __set__  
>>> john.first  
'Charles'  
>>> john.last  
'Smith'
```

The descriptor's `__set__` runs
when we assign to an attribute.

Read-only attributes

How?

```
class Person:  
    def __init__(self, first, last):  
        self._first = first  
        self._last = last
```

```
class Person:  
    def __init__(self, first, last):  
        self._first = first  
        self._last = last
```

Leading `_` is a convention:

- `_first` is “private”
- `_last` is “private”

```
class Person:  
    def __init__(self, first, last):  
        self._first = first  
        self._last = last
```

@property

```
def first(self):  
    return self._first
```

We add a property around the
“private” attribute.

```
class Person:  
    def __init__(self, first, last):  
        self._first = first  
        self._last = last  
  
    @property  
    def first(self):  
        return self._first  
  
    @property  
    def last(self):  
        return self._last
```

```
>>> john = Person("John", "Doe")
>>> john.first = "Charles"
AttributeError: ...
```

Trying to assign to
the attribute raises
an error...

```
class Person:
    def __init__(self, first, last):
        self._first = first
        self._last = last

    @property
    def first(self):
        return self._first

    @property
    def last(self):
        return self._last
```

Can we make it better?

```
class Person:  
    first = ReadOnlyAttr()  
    last = ReadOnlyAttr()  
  
    def __init__(self, first_name, last_name):  
        self._first = first_name  
        self._last = last_name  
  
    @property  
    def first(self):  
        return self._first  
  
    @first.setter  
    def first(self, value):  
        self._first = value  
  
    @property  
    def last(self):  
        return self._last  
  
    @last.setter  
    def last(self, value):  
        self._last = value
```

Read-only attributes with descriptors

```
class Person:  
    first = ReadOnlyAttr()  
    last = ReadOnlyAttr()  
  
    def __init__(self, first, last):  
        self._first = first  
        self._last = last
```

 class ReadOnlyAttr:

...

Descriptor for read-only attributes.

```
class ReadOnlyAttr:  
    def __get__(self, obj, cls):  
        ...
```

```
class Person:  
    first = ReadOnlyAttr()  
    last = ReadOnlyAttr()  
  
    def __init__(self, first, last):  
        self._first = first  
        self._last = last
```

How can the descriptor
know which attribute
we're accessing?

```
class ReadOnlyAttr:  
    def __get__(self, obj, cls):  
        ...  
  
    def __set_name__(self, cls, name):  
        ...
```

We can use the dunder
method `__set_name__`.

```
class Person:  
    first = ReadOnlyAttr()  
    last = ReadOnlyAttr()  
  
    def __init__(self, first, last):  
        self._first = first  
        self._last = last
```

Read-only attributes

```
class ReadOnlyAttr:
    def __init__(self, value):
        self._value = value
    def __get__(self, instance, owner):
        return self._value
    def __set__(self, instance, value):
        raise AttributeError("Can't set attribute")
last = ReadOnlyAttr()

def __init__(self, first, last):
    self._first = first
    self._last = last

def __set_name__(self, name):
    if name == "last":
        raise AttributeError("Can't set attribute")
```

with descriptors:

We can use the dunder method `__set_name__`

```
class ReadOnlyAttr:  
    def __get__(self, obj, cls):  
        ...  
  
    def __set_name__(self, cls, name):  
        ...
```

We can use the dunder
method `__set_name__`.

```
class Person:  
    first = ReadOnlyAttr()  
    last = ReadOnlyAttr()  
  
    def __init__(self, first, last):  
        self._first = first  
        self._last = last
```

```
class ReadOnlyAttr:  
    def __get__(self, obj, cls):  
        ...
```

```
    def __set_name__(self, cls, name):  
        ...
```

__set_name__ notifies
the descriptor of its
attribute's name.

```
class Person:  
    first = ReadOnlyAttr()  
    last = ReadOnlyAttr()  
  
    def __init__(self, first, last):  
        self._first = first  
        self._last = last
```

```
class ReadOnlyAttr:  
    def __get__(self, obj, cls):  
        ...  
  
    def __set_name__(self, cls, name):  
        self.private_attr_name = \  
            f"_{name}"
```

```
class Person:  
    first = ReadOnlyAttr()  
    last = ReadOnlyAttr()  
  
    def __init__(self, first, last):  
        self._first = first  
        self._last = last
```

self is the descriptor,
not the person.

```
class ReadOnlyAttr:  
    def __get__(self, obj, cls):  
        return getattr(←  
            obj,  
            self.private_attr_name,  
        )  
  
    def __set_name__(self, cls, name):  
        self.private_attr_name = \  
            f"_{name}"
```

```
class Person:  
    first = ReadOnlyAttr()  
    last = ReadOnlyAttr()  
  
    def __init__(self, first, last):  
        self._first = first  
        self._last = last
```

Get the value with the
private attribute name.

```
class ReadOnlyAttr:  
    def __get__(self, obj, cls):  
        return getattr(  
            obj,  
            self.private_attr_name,  
        )  
  
    def __set_name__(self, cls, name):  
        self.private_attr_name = \  
            f"_ {name}"
```

```
class Person:  
    first = ReadOnlyAttr()  
    last = ReadOnlyAttr()  
  
    def __init__(self, first, last):  
        self._first = first  
        self._last = last
```

After assignment,
`__set_name__` receives the
class and the attribute name.

```
class ReadOnlyAttr:  
    def __get__(self, obj, cls):  
        return getattr(  
            obj,  
            self.private_attr_name,  
        )  
  
    def __set_name__(self, cls, name):  
        self.private_attr_name = \  
            f"_{name}"
```

```
class Person:  
    first = ReadOnlyAttr()  
    last = ReadOnlyAttr()  
  
    def __init__(self, first, last):  
        self._first = first  
        self._last = last
```

The ReadOnlyAttr instance gets
private_attr_name = "_first"

`__set_name__` makes descriptors “aware”
of the attributes they were assigned to.

That's all folks!

A blurry, out-of-focus photograph of a person's face. The person has dark hair and appears to be wearing glasses. The lighting is dramatic, with strong red and blue hues, creating a moody or intense atmosphere.

Hell no!

I showed you enough
to get you started.

Challenges

Challenges:

- add `__set__` to RGBComponent

Challenges:

- add `__set__` to RGBComponent
- add `__set__` to ReadOnlyAttr (make it error)

Challenges:

- add `__set__` to RGBComponent
- add `__set__` to ReadOnlyAttr (make it error)
- create LogAttrAccess descriptor

What's next?

What's next?

- descriptor protocol

What's next?

- descriptor protocol
- property, staticmethod, and classmethod

What's next?

- descriptor protocol
- property, staticmethod, and classmethod
- descriptors, methods, and self
- ...
